

# CSE276C - Regression and Classification

Henrik I. Christensen

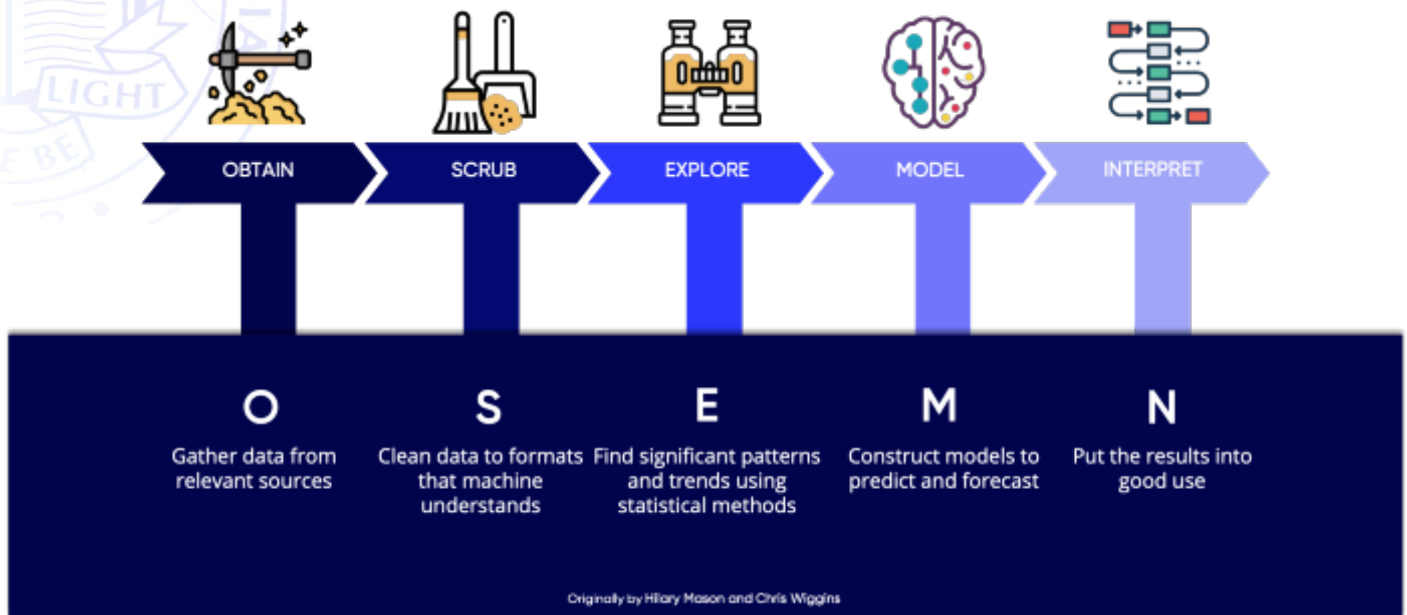

Computer Science and Engineering  
University of California, San Diego

November 2024

## Introduction

- Data science is a big part of robotics
- Many aspects of robotics rely on data analysis
  - Recognition of objects
  - Adaptive Control
  - Clean-up of sensor information
  - ...

## Data Science Process

## Outline

- 1 Introduction - Regression
- 2 Preliminaries
- 3 Linear Basis Function Models
- 4 Bayesian Linear Regression
- 5 Bayesian Model Comparison
- 6 Regression Summary
- 7 Classification
- 8 Linear Discriminant Functions
- 9 LSQ for Classification
- 10 Fisher's Discriminant Method
- 11 Perceptrons
- 12 Summary

# Introduction

- The objective of regression is to enable prediction of a value based on modeling over a data-set  $X$ .
- Consider a set of  $D$  observations over a space
- How can we generate estimates for the future?
  - Battery time?
  - Time to completion?
  - Position of doors?

## Introduction (2)

- Example

$$y(x, \mathbf{w}) = w_0 + w_1x + w_2x^2 + \dots + w_mx^m = \sum_{i=0}^m w_i x^i$$

- In general the functions could be beyond simple polynomials
- The “components” ( $\phi_i(x)$ ) are termed *basis functions*, i.e.

$$y(x, \mathbf{w}) = \sum_{i=0}^m w_i \phi_i(x) = \vec{w}^T \vec{\phi}(x)$$

## Outline

- 11 Perceptrons
- 12 Summary

# Loss Function

- For optimization we need a penalty / loss function

$$L(t, y(x))$$

- Expected loss is then

$$E[L] = \int \int L(t, y(x)) p(x, t) dx dt$$

- For the squared loss function we have

$$E[L] = \int \int \{y(x) - t\}^2 p(x, t) dx dt$$

- Goal: choose  $y(x)$  to minimize expected loss ( $E[L]$ )

# Loss Function

- Derivation of the extremum

$$\frac{\delta E[L]}{\delta y(x)} = 2 \int \{y(x) - t\} p(x, t) dt = 0$$

- Implies that

$$y(x) = \frac{\int t p(x, t) dt}{p(x)} = \int t p(t|x) dt = E[t|x]$$

# Loss Function - Interpretation

## Alternative

- Consider a small rewrite

$$\{y(x) - t\}^2 = \{y(x) - E[t|x] + E[t|x] - t\}^2$$

- The expected loss is then

$$E[L] = \int \{y(x) - E[t|x]\}^2 p(x) dx + \int \{E[t|x] - t\}^2 p(x) dx$$

## Polynomial Basis Functions

Basic Definition:

$$\phi_i(x) = x^i$$

Global functions

Small change in  $x$  affects all of them

# Gaussian Basis Functions

Basic Definition:

$$\phi_i(x) = e^{-\frac{(x-\mu_i)^2}{2s^2}}$$

A way to Gaussian mixtures, local impact

Not required to have probabilistic interpretation.

$\mu$  control position and  $s$  control scale

# Sigmoid Basis Functions

Basic Definition:

$$\phi_i(x) = \sigma\left(\frac{x - \mu_i}{s}\right)$$

where

$$\sigma(a) = \frac{1}{1 + e^{-a}}$$

$\mu$  controls location and  $s$  controls slope

# Maximum Likelihood & Least Squares

- Assume observation from a deterministic function contaminated by Gaussian Noise

$$t = y(x, w) + \epsilon \quad p(\epsilon|\beta) = N(\epsilon|0, \beta^{-1})$$

the problem at hand is then

$$p(t|x, w, \beta) = N(t|y(x, w), \beta^{-1})$$

- From a series of observations we have the likelihood

$$p(\mathbf{t}|\mathbf{X}, w, \beta) = \prod_{i=1}^N N(t_i|w^T \phi(x_i), \beta^{-1})$$

## Maximum Likelihood & Least Squares (2)

- This results in

$$\ln p(\mathbf{t}|\mathbf{w}, \beta) = \frac{N}{2} \ln \beta - \frac{N}{2} \ln(2\pi) - \beta E_D(\mathbf{w})$$

- where

$$E_D(\mathbf{w}) = \frac{1}{2} \sum_{i=1}^N \{t_i - \mathbf{w}^T \phi(x_i)\}^2$$

is the sum of squared errors

# Maximum Likelihood & Least Squares (3)

- Computing the extrema yields:

$$\mathbf{w}_{ML} = (\Phi^T \Phi)^{-1} \Phi^T \mathbf{t}$$

- where

$$\Phi = \begin{pmatrix} \phi_0(x_1) & \phi_1(x_1) & \cdots & \phi_{M-1}(x_1) \\ \phi_0(x_2) & \phi_1(x_2) & \cdots & \phi_{M-1}(x_2) \\ \vdots & \vdots & \ddots & \vdots \\ \phi_0(x_N) & \phi_1(x_N) & \cdots & \phi_{M-1}(x_N) \end{pmatrix}$$

## Line Estimation

- Least square minimization:
  - Line equation:  $y = ax + b$
  - Error in fit:  $\sum_i (y_i - ax_i - b)^2$
  - Solution:

$$\begin{pmatrix} \bar{y^2} \\ \bar{y} \end{pmatrix} = \begin{pmatrix} \bar{x^2} & \bar{x} \\ \bar{x} & 1 \end{pmatrix} \begin{pmatrix} a \\ b \end{pmatrix}$$

- So what is the problem?

# Line Estimation

- Least square minimization:
  - Line equation:  $y = ax + b$
  - Error in fit:  $\sum_i (y_i - ax_i - b)^2$
  - Solution:

$$\begin{pmatrix} \bar{y}^2 \\ \bar{y} \end{pmatrix} = \begin{pmatrix} \bar{x}^2 & \bar{x} \\ \bar{x} & 1 \end{pmatrix} \begin{pmatrix} a \\ b \end{pmatrix}$$

- So what is the problem?
- Minimizes vertical errors. Non-robust!

## LSQ on Lasers

- Line model:  $r_i \cos(\phi_i - \theta) = \rho$
- Error model:  $d_i = r_i \cos(\phi_i - \theta) - \rho$
- Optimize:  $\operatorname{argmin}_{(\rho, \theta)} \sum_i (r_i \cos(\phi_i - \theta) - \rho)^2$
- Error model derived in Deriche et al. (1)
- Well suited for “clean-up” of Hough lines

# Total Least Squares

- Line equation:  $ax + by + c = 0$
- Error in fit:  $\sum_i (ax_i + by_i + c)^2$  where  $a^2 + b^2 = 1$ .
- Solution:

$$\begin{pmatrix} \bar{x}^2 - \bar{x}\bar{x} & \bar{x}\bar{y} - \bar{x}\bar{y} \\ \bar{x}\bar{y} - \bar{x}\bar{y} & \bar{y}^2 - \bar{y}\bar{y} \end{pmatrix} \begin{pmatrix} a \\ b \end{pmatrix} = \mu \begin{pmatrix} a \\ b \end{pmatrix}$$

where  $\mu$  is a scale factor.

- $c = -a\bar{x} - b\bar{y}$

## Line Representations

- The line representation is crucial
- Often a redundant model is adopted
- Line parameters vs end-points
- Important for fusion of segments.
- End-points are less stable

- In some cases one at a time estimation is more suitable
- Also known as gradient descent

$$\begin{aligned}\mathbf{w}^{(\tau+1)} &= \mathbf{w}^{(\tau)} - \eta \nabla E_n \\ &= \mathbf{w}^{(\tau)} - \eta (t_n - \mathbf{w}^{(\tau)T} \phi(x_n)) \phi(x_n)\end{aligned}$$

- Known as least-mean square (LMS). An issue is how to choose  $\eta$ ?

## Regularized Least Squares

- As seen in previous lecture sometime control of parameters might be useful.
- Consider the error function:

$$E_D(\mathbf{w}) + \lambda E_W(\mathbf{w})$$

- which generates

$$\frac{1}{2} \sum_{i=1}^N \{t_i - \mathbf{w}^T \phi(x_i)\}^2 + \frac{\lambda}{2} \mathbf{w}^T \mathbf{w}$$

- which is minimized by

$$\mathbf{w} = (\lambda \mathbf{I} + \Phi^T \Phi)^{-1} \Phi^T \mathbf{t}$$

- 12 Summary

## Bayesian Linear Regression

- Define a conjugate prior over  $w$

$$p(w) = N(w|m_0, S_0)$$

- given the likelihood function and regular from Bayesian analysis we can derive

$$p(w|t) = N(w|m_N, S_N)$$

- where

$$\begin{aligned} m_N &= S_N (S_0^{-1} m_0 + \beta \Phi^T t) \\ S_N^{-1} &= S_0^{-1} + \beta \Phi^T \Phi \end{aligned}$$

# Bayesian Linear Regression (2)

- A common choice is
- So that

$$p(w) = N(w|0, \alpha^{-1}I)$$

$$\begin{aligned} m_N &= \beta S_N \Phi^T t \\ S_N^{-1} &= \alpha I + \beta \Phi^T \Phi \end{aligned}$$

## Example - No Data

## Example - 1 Data Point

## Example - 2 Data Points

# Example - 20 Data Points

## Outline

- 1 Introduction - Regression
- 2 Preliminaries
- 3 Linear Basis Function Models
- 4 Bayesian Linear Regression
- 5 Bayesian Model Comparison**
- 6 Regression Summary
- 7 Classification
- 8 Linear Discriminant Functions
- 9 LSQ for Classification
- 10 Fisher's Discriminant Method
- 11 Perceptrons
- 12 Summary

- How does one select an appropriate model?
- Assume for a minute we want to compare a set of models  $M_i$ ,  $i \in 1, \dots, L$  for a dataset  $D$
- We could compute

$$p(M_i|D) \propto p(D|M_i)p(M_i)$$

- Bayes Factor: Ratio of evidence for two models

$$\frac{p(D|M_i)}{p(D|M_j)}$$

## The mixture distribution approach

- We could use all the models:

$$p(t|x, D) = \sum_{i=1}^L p(t|x, M_i, D)p(M_i|D)$$

- Or simply go with the most probably/best model.

- We can compute model evidence

$$p(D|M_i) = \int p(D|w, M_i)p(w|M_i)dw$$

- Allow computation of model fit based on parameter range

## Evaluation of Parameters

- Evaluation of posterior over parameters

$$p(w|D, M_i) = \frac{P(D|w, M_i)p(w|M_i)}{P(D|M_i)}$$

- There is a need to understand how good is a model?

- Consider evaluation of a model w. parameters  $w$

$$p(D) = \int p(D|w)p(w)dw \approx p(D|w_{map}) \frac{\sigma_{posterior}}{\sigma_{prior}}$$

- Then

$$\ln p(D) \approx \ln p(D|w_{map}) + \ln \left( \frac{\sigma_{posterior}}{\sigma_{prior}} \right)$$

## Model Comparison as Kullback-Leibler

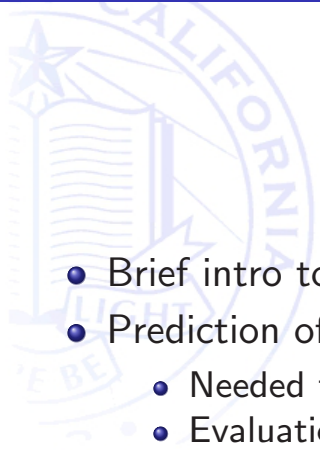

- From earlier we have comparison of distributions

$$KL = \int p(D|M_1) \ln \frac{p(D|M_1)}{p(D|M_2)} dD$$

- Enables comparison of two different models

## Classification Introduction

- 
- Linear classification of data
    - Basic pattern recognition
    - Separation of data: buy/sell
    - Segmentation of line data, ...

# Simple Example - Bolts or Needles

## Classification

- Given
  - An input vector:  $X$
  - A set of classes:  $c_i \in \mathcal{C}$ ,  $i = 1, \dots, k$
- Mapping  $m : X \rightarrow \mathcal{C}$
- Separation of space into decision regions
- Boundaries termed decision boundaries/surfaces

- It is a 1-of-K coding problem
- Target vector:  $\mathbf{t} = (0, \dots, 1, \dots, 0)$
- Consideration of 3 different approaches
  - 1 Optimization of discriminant function
  - 2 Bayesian Formulation:  $p(c_i|x)$
  - 3 Learning & Decision fusion

## Code for experimentation

- There are data sets and sample code available
  - NETLAB: <http://www.ncrg.aston.ac.uk/netlab/index.php>
  - Kaggle: <https://www.kaggle.com>
  - Lots of good robotics data-sets too

- 6 Regression Summary
- 7 Classification
- 8 Linear Discriminant Functions
- 9 LSQ for Classification
- 10 Fisher's Discriminant Method
- 11 Perceptrons
- 12 Summary

## Discriminant Functions

- Objective: input vector  $\mathbf{x}$  assigned to a class  $c_i$
- Simple formulation:

$$y(\mathbf{x}) = \mathbf{w}^T \mathbf{x} + w_0$$

- $\mathbf{w}$  is termed a weight vector
- $w_0$  is termed a bias
- Two class example:  $c_1$  if  $y(\mathbf{x}) \geq 0$  otherwise  $c_2$

- Two points on decision surface  $\mathbf{x}_a$  and  $\mathbf{x}_b$
- $y(\mathbf{x}_a) = y(\mathbf{x}_b) = 0 \Rightarrow \mathbf{w}^T(\mathbf{x}_a - \mathbf{x}_b) = 0$
- $\mathbf{w}$  perpendicular to decision surface

$$\frac{\mathbf{w}^T \mathbf{x}}{\|\mathbf{w}\|} = -\frac{w_0}{\|\mathbf{w}\|}$$

- Define:  $\tilde{\mathbf{w}} = (w_0, \mathbf{w})$  and  $\tilde{\mathbf{x}} = (1, \mathbf{x})$  so that:

$$y(\mathbf{x}) = \tilde{\mathbf{w}}^T \tilde{\mathbf{x}}$$

## Linear discriminant function

# Multi Class Discrimination

- Generation of multiple decision functions

$$y_k(\mathbf{x}) = \mathbf{w}_k^T \mathbf{x} + w_{k0}$$

- Decision strategy

$$j = \arg \max_{i \in 1..k} y_i(\mathbf{x})$$

## Multi-Class Decision Regions

# Example - Bolts or Needles

## Minimum distance classification

- Suppose we have computed the mean value for each of the classes
- $m_{needle} = [0.86, 2.34]^T$  and  $m_{bolt} = [5.74, 5.85]^T$
- We can then compute the minimum distance

$$d_j(x) = \|x - m_j\|$$

- $\operatorname{argmin}_i d_i(x)$  is the best fit
- Decision functions can be derived

# Bolts / Needle Decision Functions

Needle  $d_{needle}(x) = 0.86x_1 + 2.34x_2 - 3.10$

Bolt  $d_{bolt}(x) = 5.74x_1 + 5.85x_2 - 33.59$

Decision boundary

$$d_i(x) - d_j(x) = 0$$

$$d_{needle/bolt}(x) = -4.88x_1 - 3.51x_2 + 30.49$$

## Example decision surface

  - 10 Fisher's Discriminant Method
  - 11 Perceptrons
  - 12 Summary

## Least Squares for Classification

- 
- Just like we could do LSQ for regression we can perform an approximation to the classification vector  $\mathcal{C}$
  - Consider again

$$y_k(\mathbf{x}) = \mathbf{w}_k^T \mathbf{x} + w_{k0}$$

- Rewrite to

$$\mathbf{y}(\mathbf{x}) = \tilde{\mathbf{W}}^T \tilde{\mathbf{x}}$$

- Assuming we have a target vector  $\mathbf{T}$

# Least Squares for Classification

- The error is then:

$$E_D(\tilde{\mathbf{W}}) = \frac{1}{2} \text{Tr} \left\{ (\tilde{\mathbf{X}}\tilde{\mathbf{W}} - \mathbf{T})^T (\tilde{\mathbf{X}}\tilde{\mathbf{W}} - \mathbf{T}) \right\}$$

- The solution is then

$$\tilde{\mathbf{W}} = \left( \tilde{\mathbf{X}}^T \tilde{\mathbf{X}} \right)^{-1} \tilde{\mathbf{X}}^T \mathbf{T}$$

## LSQ and Outliers

- 1 Introduction - Regression
- 2 Preliminaries
- 3 Linear Basis Function Models
- 4 Bayesian Linear Regression
- 5 Bayesian Model Comparison
- 6 Regression Summary
- 7 Classification
- 8 Linear Discriminant Functions
- 9 LSQ for Classification
- 10 Fisher's Discriminant Method
- 11 Perceptrons
- 12 Summary

## Fisher's linear discriminant

- Selection of a decision function that maximizes distance between classes
- Assume for a start

$$y = \mathbf{W}^T \mathbf{x}$$

- Compute  $m_1$  and  $m_2$

$$\mathbf{m}_1 = \frac{1}{N_1} \sum_{i \in C_1} \mathbf{x}_i \quad \mathbf{m}_2 = \frac{1}{N_2} \sum_{j \in C_2} \mathbf{x}_j$$

- Distance:

$$m_2 - m_1 = \mathbf{w}^T (\mathbf{m}_2 - \mathbf{m}_1)$$

- where  $m_i = \mathbf{w} \mathbf{m}_i$

# The sub-optimal solution

## The Fisher criterion

- Consider the expression

$$J(\mathbf{w}) = \frac{\mathbf{w}^T \mathbf{S}_B \mathbf{w}}{\mathbf{w}^T \mathbf{S}_W \mathbf{w}}$$

- where  $\mathbf{S}_B$  is the between class covariance and  $\mathbf{S}_W$  is the within class covariance, i.e.

$$\mathbf{S}_B = (\mathbf{m}_1 - \mathbf{m}_2)(\mathbf{m}_1 - \mathbf{m}_2)^T$$

and

$$\mathbf{S}_W = \sum_{i \in \mathcal{C}_1} (\mathbf{x}_i - \mathbf{m}_1)(\mathbf{x}_i - \mathbf{m}_1)^T + \sum_{i \in \mathcal{C}_2} (\mathbf{x}_i - \mathbf{m}_2)(\mathbf{x}_i - \mathbf{m}_2)^T$$

- Optimized when

$$(\mathbf{w}^T \mathbf{S}_B \mathbf{w}) \mathbf{S}_W \mathbf{w} = (\mathbf{w}^T \mathbf{S}_W \mathbf{w}) \mathbf{S}_B \mathbf{w}$$

or

$$\mathbf{w} \propto \mathbf{S}_W^{-1}(\mathbf{m}_2 - \mathbf{m}_1)$$

# The Fisher result

## Generalization to $N > 2$

- Define a stacked weight factor

$$\mathbf{y} = \mathbf{W}^T \mathbf{x}$$

- The within class covariance generalizes to

$$\mathbf{S}_w = \sum_{k=1}^K \mathbf{S}_k$$

- The between class covariance is

$$\mathbf{S}_B = \sum_{k=1}^K N_k (\mathbf{m}_k - \mathbf{m})(\mathbf{m}_k - \mathbf{m})^T$$

- It can be shown that  $J(\mathbf{w})$  is optimized by the eigenvectors to the equation

$$\mathbf{S} = \mathbf{S}_w^{-1} \mathbf{S}_B$$

- 12 Summary

## Perceptron Algorithm

- Developed by Rosenblatt (1962)
- Formed an important basis for neural networks
- Use a non-linear transformation  $\phi(\mathbf{x})$
- Construct a decision function

$$y(\mathbf{x}) = f(\mathbf{w}^T \phi(\mathbf{x}))$$

- where

$$f(a) = \begin{cases} +1, & a \geq 0 \\ -1, & a < 0 \end{cases}$$

# The perceptron criterion

- Normally we want

$$\mathbf{w}^T \phi(\mathbf{x}_n) > 0$$

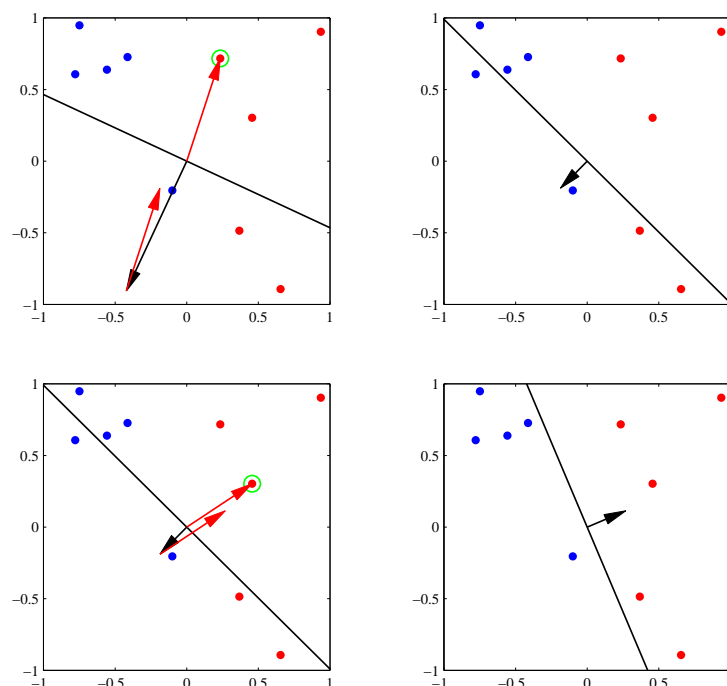

- Given the target vector definition

$$E_p(\mathbf{w}) = - \sum_{n \in \mathcal{M}} \mathbf{w}^T \phi_n t_n$$

- Where  $\mathcal{M}$  represents all the mis-classified samples
- We can make this a gradient descent as seen in last lecture

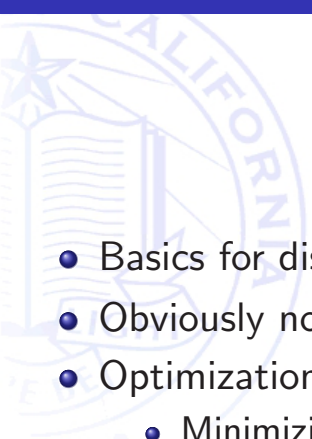

$$\mathbf{w}^{(\tau+1)} = \mathbf{w}^{(\tau)} - \eta \nabla E_p(\mathbf{w}) = \mathbf{w}^{(\tau)} + \eta \phi_n t_n$$

## Classification Summary

- 
- Basics for discrimination / classification
  - Obviously not all problems are linear
  - Optimization of the distance/overlap between classes
    - Minimizing the probability of error classification
  - Basic formulation as an optimization problem
  - How to optimize between cluster distance? Covariance Weighted
  - Basic recursive formulation
  - Could we make it more robust?

- Data models are anchored in pure data driven or model based evaluation
- How can we use models to interpret data and extrapolate beyond the basic data?
- Covered basic models for regression and classification.
